SHORT ANSWER. Write the word or phrase that best completes each statement or answers the question.

Provide a short answer.

375) Suppose the population of deer fluctuates over time. The population increases in the summer and decreases in the winter. It also varies over many years as well. If you looked at the graph of population versus time, would this relation be a function? Why or why not?

Answer: This would be a function because at any given time there is only one possible population. Despite the fact that the population can reach the same level several times this is still a function, but for each point in time, there can be no more than one population.

376) Consider the linear function $f(x) = 5x + 20$. What is the domain and range of this function? Now, suppose the function represents the relationship between studying time and grades on an exam. The variable x represents the number of hours spent studying and f(x) represents the grade on the exam. Does this change the domain and range? If so, what is the new domain and range and why is it different?

Answer: The domain is all real numbers and the range is the set of all real numbers. In the context of exam grades, the domain and range both become the set of nonegative real numbers. In this context, times and grades less than zero do not make sense.

377) If a company decides to make a new product, there are fixed costs and variable costs associated with this new product. Explain the differences of the two types of costs and why they occur. Use an example to illustrate your point.

Answer: Fixed costs occur only once. These costs may be startup costs related to the production of the new product. Variable costs depend on how much product is made. These costs may consist of labor, material, and maintenance.

For example, a company decided to make oak filing cabinets. Fixed costs would include the costs of purchasing and renovating plant space and the cost of manufacturing equipment. Variable costs would include the cost labor and the cost of materials.

378) Suppose you have to develop a model to predict snowfall for the upcoming winter based on data from previous winters. Consider the table of annual snowfall over the last five years:

Snowfall (y) (in inches)	180	168	163	155	165
year (x)	1994	1995	1996	1997	1998

Would it be possible to come up with one model that predicted very low amounts of snowfall and another that predicted very high amounts of snowfall? How so? If you were employed by a ski resort to come up with a model, what type of model would you use? What could be done to try to reduce the chance of coming up with such different models?

Answer: Linear Regression would provide a low snowfall prediction, and quadratic regression would provide a high snowfall prediction. Because ski resorts depend on snowfall, a model that predicts a greater amount of snow would be more useful for advertising purposes. Considering the pattern of snowfall over a longer period of time would provide a more accurate prediction than simply considering a five year period and hence would reduce the potential for finding conflicting models.

Answer: B

119) Why does the general continuity principle regarding the quotient $g(x)/f(x)$ include the phrase "so long as the inputs x do not yield outputs $f(x) = 0$"?

A) Whenever $f(x) = 0$, the function $g(x)/f(x)$ is so large that it would be difficult to graph it.

B) One needs to avoid an infinite $g(x)$.

C) The function $g(x)/f(x)$ is not defined for any x such that $f(x) = 0$, and a function cannot be continuous at any point at which it is undefined.

D) The quotient $g(x)/f(x)$ is an invalid function unless there is no x for which $f(x) = 0$.

Answer: C

B) If $\lim\limits_{x \to a} g(x) = M$ and $\lim\limits_{x \to a} f(x) = L$, then $\lim\limits_{x \to a} \dfrac{g(x)}{f(x)} = \dfrac{\lim\limits_{x \to a} g(x)}{\lim\limits_{x \to a} f(x)} = \dfrac{M}{L}$, provided that $f(a) \neq 0$.

C) $\lim\limits_{x \to a} \dfrac{g(x)}{f(x)} = \dfrac{g(a)}{f(a)}$.
